

STORYLINE

Read the titles top-to-bottom — they tell the whole argument.

- 1. Recommendation: discontinue CRV on the IM banner
- 2. Executive summary
- 3. We understand both campaigns & the test is valid
- 4. Who we'd suppress: recurring installment users
- 5. The net trade: who we lose vs who we gain
- 6. Targeting & robustness
- 7. Three things to close the final number

7 frames · audience: senior cross-LOB (PCL + CRV)

CARDS POD · VALUE MANAGEMENT

Discontinue CRV on the IM online banner — the PCL we recover is worth far more than the CRV we give up

CRV × PCL cannibalization · bulletproof re-analysis · Oct 2024 – Apr 2026

Decision asked of this room: approve discontinue (or throttle) of CRV on the mobile banner

EXECUTIVE SUMMARY

Running CRV on the mobile banner suppresses a higher-value product; stopping it is net positive

- **It's real & causal.** PCL converts **1.08pp lower** when CRV is co-present (17.2%→16.2%), significant in 17 of 20 months on a valid randomized holdout.
- **It's genuine loss, not a swap.** ~72% of recovered PCL is net-new demand; only ~28% would have been a CRV→PCL switch.
- **The trade favours PCL.** PCL recovered at **\$675/conversion** dwarfs CRV forgone at **\$36/installment** — even counting every installment plan we'd lose.
- **Soft landing exists.** Harm concentrates in high PCL-propensity clients, so a throttle captures most of the value.

FOUNDATION · WHY YOU CAN TRUST THE READ

We understand how both campaigns run, and the comparison is a valid, balanced experiment

✓ **Both campaigns mapped.** CRV is always-on (~21 waves/mo, ~92-day offers); PCL deploys ~4.4 waves/mo into the same mobile surface. **Q00**

✓ **Arms are comparable.** CRV-Action and CRV-Control overlap PCL at 28% vs 27% — a real randomized holdout survives in the overlap. **Q01**

✓ **The collision is large.** 67% of mobile PCL deployments run head-to-head with an active CRV offer. **Q03**

One line for the room: this is not an observational comparison — it's an A/C holdout, so the PCL gap we show next is *caused* by CRV, not by who the clients are. The Q00–Q03 detail lives in the appendix.

3 / 7

CRV converters aren't one-and-done buyers — they're **recurring installment users**, so the loss must be counted in plans, not conversions

~6.85

installment plans per converting client (20-mo window)

~\$980

principal per plan · ~\$6.7k cumulative / client

6.6% / 6.6mo

APR / term — flat across all cohorts

Why the profile matters:

per-unit economics are flat across Action/Control and overlap/no-overlap — so we're not suppressing a richer or riskier book, just *more of the same* recurring behavior. That removes the "you're killing your best CRV customers" objection and tells us exactly what \$36 multiplies: the plan count from Q13.

Source: bulletproof_analysis Q05 (n transactions excluded — 6-month); Q13 supplies the clean plan count · METRICS_DICTIONARY.md 4 / 7

The unit that decides the loss: valuing CRV at \$36/installment means we must count **installment plans**, not the binary "did it convert or not"

THE NET TRADE

Most recovered PCL is demand CRV was suppressing to zero — and at \$675 vs \$36 the recovered value **far outweighs** the CRV given up

Where the recovered PCL comes from

Net-new — was converting nothing · 72%

Swap · 28%

Only ~28% were already converting CRV; stop CRV and that demand routes to PCL. The other ~72% is pure lift.

Q07 · substitution test

SIDE	UNITS × VALUE	\$
PCL recovered	42K–70K conv × \$675	+\$28.6M to +\$47.3M *
CRV forgone	29,224 conv × \$36	–\$1.1M
CRV forgone (plan-adj.)	~200K plans × \$36	–\$7.2M †
Net	—	+\$21M to +\$46M

Source: bulletproof_analysis Q07, Q06, Q13 · PCL \$675 confirmed · CRV \$36/installment working assumption
*PCL base moves with the suppression window (6- vs 12-mo).
†Plan-adjusted = 29,224 × ~6.85 plans/converter — a little more than the 20-mo window at Q13

TARGETING & ROBUSTNESS

Cannibalization is top-heavy in PCL-propensity, so a throttle is a credible soft landing — and the effect survives every robustness check

PCL gap (Control – Action), pp, by PCL-propensity decile (1 = most likely)

Decile	PCL gap
D1	+2.15
D2	+0.93
D3	+0.61
D4	+0.57
D5	+0.34
D6	+0.36
D7	+0.05
D8	+0.04
D9	+0.04
D10	+0.38

Read with care:

these are **PCL-propensity** deciles — we do **not** have a CRV decile. We target the throttle by where PCL is most cannibalized (the right lever); we make **no** per-decile CRV-value claims.

It's not a timing or duration artifact:

- Gap is the same whether CRV or PCL arrives first **Q09**
- Gap is flat regardless of how long the overlap lasts **Q12**
- Exposed clients also convert ~2–4 days slower **Q12** → a fixed concurrent-competition penalty.

Q08 · deciles

TO CLOSE THE NUMBER

The direction is locked; three inputs turn the net into a single defensible figure

INPUT · external

1 · Confirm CRV value

Replace the \$36/installment placeholder with William's actual NIBT, on a per-installment basis so it matches the Q13 plan count.

Q13 · built, not run

2 · Run the clean unit counts

Incremental converting clients and installment plans per arm → the real CRV-loss base, valued at the confirmed \$36.

Decision · scope

3 · Set the suppression window

6- vs 12-month suppression sets the incremental PCL base (~42K vs ~70K), turning the gain from a range into a point.

Net message:

every robustness check points the same way — causal, incremental, order- and dose-independent. What's left is one value input, one query run, and one scope decision — not whether the effect is real.
